

The newtxtt Package*

Michael Sharpe

March 3, 2024

There is a relative paucity of free serifed typewriter fonts available for use in L^AT_EX—`courier` and (extensions of) `cmtt` are the most common. In my opinion, `cmtt` and its enhancements, especially `zlmtt`, are a much better choice than `courier` in almost every circumstance, as the latter is so light and so wide that it looks poor on screen and causes endless problems with overfull boxes. (The ratio of their glyph widths is $723/525 \approx 1.38$.) This package provides an interface to another alternative—the typewriter fonts provided with `txfonts`, with some enhancements. They have the same widths as `cmtt`, but are taller, heavier, more geometric and less shapely, with very low contrast, and are more suited to match Roman fonts of height and weight approximating that of Times. This package, loaded with

```
\usepackage{newtxtt} % options can be added
```

provides access to its features, no matter what other text fonts you might be using. It should be placed after all your other text font loading packages that might contain instructions to change `\ttdefault`, and before loading math packages so that the math packages can make a suitable definition of `\mathtt`. With no options specified, as above, you'll get full functionality as a monospaced typewriter font family, with typewriter text rendered using essentially `txtt`, but with a five choices for the glyph 'zero'. In addition, the package provides italic (slanted) and bold versions, plus small caps in regular (medium) and bold weights, upright shape only. It is offered only in T1 (plus full TS1) encoding. The macros `\ttdefault`, `\ttfamily`, `\texttt` and the obsolete but convenient macro `\tt` may be used to access this font. The package provides, by means of options or macros, an alternate form of `newtxtt` with names containing a 'z', differing from it in some important ways:

- the interword spacing is no longer the same as the glyph spacing, but is variable though generally smaller—`fontdimen` settings have been changed to resemble those of text fonts;
- where monospaced typewriter fonts typically add an extra space with full width at the end of a sentence, the modified 'z' version adds a considerably smaller space;
- hyphenation is not suppressed.

These features may be accessed by means of the new macros `\ttzdefault`, `\ttzfamily`, `\textttz` and `\ttz` which are in all ways analogous to their monospace cousins. (Verbatim modes will continue to use the monospaced version.) The purpose of the `ttz` version to allow use of `newtxtt` for blocks of TypeWriter-like text, though not monospaced and respecting right justification. E.g.,

*It is a pleasure to thank Jean-François Burnol who has offered very useful advice and feedback on this package. For an extensive example of its usage as body text, see the documentation of his remarkable `xint` package.
