

# The `jsonparse` package

A handy way to parse, store and access JSON data from files or strings in LaTeX documents

Jasper Habicht \*

Version 1.7.3, released on 10 June 2026

---

## 1 Introduction

Hello guys, I am Jason, the JSON parsing horse. JSON data is my favorite thing to parse! But I found that converting JSON to TeX can be a bit tricky. Therefore, I created this package which I am happy to introduce to you. \*\*

The `jsonparse` package provides a handy way to read in JSON data from files or strings in LaTeX documents, parse the data and store it in a user-defined token variable. The package allows accessing the stored data via a JavaScript-flavored syntax.

The package is continuously being tested, but bugs cannot be ruled out. The author is grateful for reporting any bugs via GitHub at <https://github.com/jasperhabicht/jsonparse/issues>. A site for asking questions about the package and for suggestions for improvement is available at <https://github.com/jasperhabicht/jsonparse/discussions>.

## 2 Frequently asked questions

### 2.1 Why does a comparison of two equal strings return false?

Note that you probably need to use `\JSONParseExpandableValue` if you want to compare a value from parsed JSON data with the contents of another token list. See the explanation [below](#) for more details.

Also note that `\JSONParseExpandableValue` returns a string with specific category codes, namely category code 12 (“other”) for all characters except spaces. Therefore, you need to test against another string. You can use `\detokenize` for conversion. See [section 4](#) for more information.
